

A File System for Laptops

Brian L. Stuart

University of Memphis

4th International Workshop on Plan 9

The Context

- ▶ When UNIX was almost 20 years old, there came Plan 9
- ▶ Computing environment was qualitatively different
 - ▶ Graphics, networks, workstations
- ▶ Plan 9 is now over 20 years old
- ▶ What's different?

What's Changed

Laptops

Why are Laptops so Different

- ▶ File Servers are good things
 - ▶ Centerpieces of good networks, and of Plan 9
 - ▶ Centralize state
 - ▶ (Mostly) Stateless workstations
- ▶ Laptops are anything but central
- ▶ Laptops must be stateful

The Usual Solutions

- ▶ tar, rsync, and friends
 - ▶ Laptop copy is the “real” one
 - ▶ File server is backup

The Answer

- ▶ Reverse the perspective
 - ▶ File server copy is the “real” one
 - ▶ Laptop is a cache

First Approach

- ▶ Oriented around files
- ▶ Effectively mapped one directory tree to another
- ▶ Spent a lot of time doing stats

New Approach

- ▶ Bi-directional tee for Styx messages
- ▶ Message oriented
- ▶ Write-through cache when connected
- ▶ Write-back cache when disconnected

When Connected

- ▶ All messages go to file server
- ▶ Most (ex. Tread, Tstat) also go to cache
- ▶ Rread and Rstat from the file server are changed into Twrite and Twstat for the cache
- ▶ Twalk is complicated
 - ▶ Walk on both the file server and the cache
 - ▶ Generate Tcreate for each path element missing from the cache

When Disconnected

- ▶ All messages go to the cache
- ▶ Most (ex. Tversion, Tauth, Tread, Tstat) are written to a log
- ▶ Log is played back to the file server when reconnected

Status

- ▶ Major parts implemented and working
 - ▶ Connected mode
 - ▶ Disconnected mode with untested write-back log
- ▶ Major parts not implemented
 - ▶ Testing write-back log
 - ▶ Log playback on reconnect
